AB A highly sensitive method is provided for detecting a cytokine (e.g., CXC chemokine, stromal-derived factor-1) in a body fluid (e.g., serum, whole blood) sample by a **time-resolved** fluorescence immunoassay (TR-FIA). The method comprises a process for forming on a solid phase a complex composed of a trapped cytokine and a fluorescent moiety forming a coordination structure with a **lanthanoid** metal (e.g., **europium**), and a process for measuring the fluorescence from the fluorescent moiety. The complex is formed by binding five components sequentially in this order: (a) a first antibody possessing a

moiety bound to the solid phase and a region capable of binding with cytokine; (b) cytokine; (c) a second antibody possessing a region capable of binding with cytokine and a moiety bound with **biotin**; (d) a connector possessing streptavidin or avidin and a fluorescent moiety capable of forming a coordination structure with a **lanthanoid** metal ion; and (e) a **lanthanoid** metal ion. The fluorescent moiety (e.g., 4,4'-bis(1",1",1",2",2",3",3"-heptafluoro-4",6"-hexadione-6"-yl)-sulfo-o-terphenyl) is represented by the general formula 3,5-(C3F7COCH2CO-p-C6H4)C6H3SO3N.

PRIORITY APPLN. INFO.:			JP 1998-346878	19981207

AB A new, convenient and highly sensitive anal. method is provided for measuring an antigen, an antibody, or a nucleic acid (e.g, DNA, RNA) using an antibody, an antigen or a probe, resp., as a ligand labeled with a fluorescent substance. The first ligand capable of specifically binding with an objective substance for anal. is immobilized within a range of excitation light irradiation or a central region on the reaction vessel surface holding a sample. This immobilized first ligand is made contact with a sample for anal., and with a fluorescent substance-labeled second ligand capable of specifically binding with the objective substance for anal. at the site different from the first ligand. Upon irradiating the excitation light specific to the fluorescent label substance, the

fluorescence is detected from the label on the second ligand bound with the complex between the immobilized first ligand and the objective substance for anal. Human  $\alpha$ -fetoprotein (AFP) in a blood sample was measured with a high sensitivity by this method using anti-human AFP monoclonal antibody and a combination of **biotin**-labeled anti-AFP polyclonal antibody and **europium**-labeled streptavidin-BSA polymer.

AB A method for the spectroscopic determination of a marker comprises: (a) contacting

chelated **lanthanide** metal ions bound to a marker with a buffered solution comprising a detergent, an enhancer reagent and a polyanion, wherein said buffer maintains the pH of the solution within the range of about 3.5 to about 11.5 and said polyanion is present in sufficient concentration such that said **lanthanide** metal ion disassociates from said chelate complex and reassociates with said enhancer reagent, thereby transferring said **lanthanide** metal ion into fluorescent form; and (b) determining the amount of **lanthanide** metal ion liberated from the marker as a measure of the amount of marker present by subjecting the solution to a short radiation

pulse and detecting the fluorescence of the **lanthanide** metal ion after the fluorescence from any background sources substantially has ceased. A HIV-1 p24 ELISA with **time-resolved** fluorescence detection used anti-p24 monoclonal antibody-coated wells, biotinylated rabbit anti-p24 antibodies, and streptavidin-**europium** EDTA chelate conjugate. The enhancement solution contained 2-naphthoyltrifluoroacetone, trioctylphosphine oxide, citrate (or L-malate), imidazole and Triton X-100. The sensitivity was 1 pg/mL with a dynamic range from 0.0-1000 pg/mL.

AB A new **europium** fluorescent chelate, 4,4'-bis(1",1",1",2",2",3",3"-heptafluoro-4",6"-hexanedione-6"-yl)-chlorosulfo-o-terphenyl (BHHCT)-Eu<sup>3+</sup>, was used as a label for highly sensitive **time-resolved** fluoroimmunoassay of human IgE. Two assay formats were employed in the anal. In the first format, an immuno-conjugate of rabbit anti-human IgE antibody-human IgE-biotinylated goat anti-human IgE antibody-BHHCT-Eu<sup>3+</sup>-labeled SA (or BHHCT-Eu<sup>3+</sup>-labeled BSA-SA; BSA, bovine serum albumin; SA, streptavidin) was used for measurement. The method gives the detection limits of 3.6+10<sup>-2</sup> IU/mL (labeled SA) and 1.1+10<sup>-2</sup> IU/mL (labeled SA-BSA). In the second format, an immunoconjugate of goat anti-human IgE antibody-human IgE-rabbit anti-human IgE antibody-biotinylated goat anti-rabbit IgG antibody-BHHCT-Eu<sup>3+</sup>-labeled SA (or BHHCT-Eu<sup>3+</sup>-labeled BSA-SA) was used for measurement. The detection limits of these methods are 3.0+10<sup>-3</sup> IU/mL (labeled SA) and 1.5+10<sup>-3</sup> IU/mL (labeled BSA-SA). The above detection limits are one to two orders of magnitude lower than those of the conventional RIA and enzyme immunoassay. The CV of the present method is less than 7%, and the recovery is in the range of 85-105% for serum samples.

AB The application of a complex of Eu<sup>3+</sup> with tetradentate beta-diketone ligand (its structure on the top of page 2; here: R = chlorosulfonyl, isothiocyano, NH<sub>2</sub>, or hydrazinesulfonyl and R<sub>1</sub> = C<sub>1</sub>-5 alkyl, C<sub>1</sub>-5 perfluoroalkyl, Ph, or perfluorophenyl) as fluorescent marker for labeling protein (such as antibody, antigen, **avidin**, **streptavidin**, bovine serum albumin, or hapten-BSA conjugate) is presented. The process for labeling protein comprises dissolving protein in NaHCO<sub>3</sub> buffer (its pH 9.0-9.5), allowing to react with beta-diketone at room temperature for 1-2 h, removing the un- reacted beta-diketone via dialysis or column chromatog., chelating with EuCl<sub>3</sub> solution, adding antiseptic and protein activity stabilizing agent, and storing at low temperature. The molar ratio of beta-diketone to Eu<sup>3+</sup> is 1:1-2. The labeled protein may be used for determination

of bioactive substance by **time-resolved** fluorometry.

AB A covalent binding-copolymn. method was developed to prepare silica-based fluorescent **europium** nanoparticles that can be used for biolabeling and highly sensitive **time-resolved** fluorescence bioassays. The nanoparticles were prepared in a water-in-oil (W/O) microemulsion consisting of a conjugate of (3-aminopropyl)triethoxysilane bound to a fluorescent Eu<sup>3+</sup> chelate, 4,4''-bis(1'',1'',1'',2'',2'',3'',3''-heptafluoro-4'',6''-hexanedion-6''-yl)chlorosulfo-o-terphenyl-Eu<sup>3+</sup> (APS-BHHCT-Eu<sup>3+</sup>), free (3-aminopropyl)triethoxysilane (APS), tetra-Et orthosilicate (TEOS), Triton X-100, n-octanol, water, and cyclohexane by copolymn. of APS-BHHCT-Eu<sup>3+</sup>, APS, and TEOS with aqueous ammonia. Characterization by TEM and fluorometric methods indicate that the nanoparticles are spherical and uniform in size, 36±4 nm in diameter, highly photostable, and strongly fluorescent, having a fluorescence quantum yield of 50.6% and a long fluorescence lifetime of 384 μs. The amino groups directly introduced

to the surface of the nanoparticles by using free (3-aminopropyl)triethoxysilane in the nanoparticle preparation made the surface modification and bioconjugation of the nanoparticles easier. The nanoparticles were used for **streptavidin** labeling, and the nanoparticle-labeled **streptavidin** was used in sandwich-type **time-resolved** fluoroimmunoassays (TR-FIA) of carcinoembryonic antigens (CEA) and hepatitis B surface antigens (HBsAg) in human sera. The methods give detection limits of 1.9 pg ml<sup>-1</sup> for CEA, and 23 pg ml<sup>-1</sup> for HBsAg. The concns. of HBsAg in 30 human serum samples were determined, and the results were compared with those independently determined

by an established TR-FIA method using the BHHCT-Eu<sup>3+</sup>-labeled **streptavidin**. A good correlation was obtained with a correlation coefficient of 0.993.

AB Novel fluorescent **europium**(III) chelate-doped silica nanoparticles were prepared and characterized as a new type of fluorescence probe for quant. bioassay. The preparation was carried out in a water-in-oil (w/o) microemulsion consisting of a strongly fluorescent Eu<sup>3+</sup> chelate, 4,4''-bis(1'',1'',1'',2'',2'',3'',3''-heptafluoro-4'',6''-hexanedion-6''-yl)-o-terphenyl-Eu<sup>3+</sup> (BHHT-Eu<sup>3+</sup>), surfactant (Triton X-100), co-surfactant

(n-hexanol, n-heptanol or n-octanol), aqueous phase (H<sub>2</sub>O or D<sub>2</sub>O) and oil phase (cyclohexane) by controlling the hydrolysis of tetraethylorthosilicate (TEOS). The effects of different co-surfactants and aqueous phases on the size and fluorescence lifetime of the nanoparticles were investigated. The results reveal that the size of the nanoparticles is decreased with a change of co-surfactants from n-hexanol to n-octanol, and the fluorescence lifetime of the nanoparticles is increased with a change of aqueous phase from H<sub>2</sub>O to D<sub>2</sub>O. A new method was established for the surface modification and bioconjugation of the nanoparticles. Nanoparticle-labeled **streptavidin** (SA) was used for the **time-resolved** fluoroimmunoassay of human hepatitis B surface antigen (HBsAg). The result shows that the new fluorescent **europium**(III) chelate-doped silica nanoparticles are suitable to be used as a fluorescence probe for highly sensitive bioassays.

AB A method for nucleic acid detection using oligonucleotide primers labeled				

with fluorescent substance containing **lanthanide** chelate, represented by a formula Ln-S-dNTP (Ln = **lanthanide** metal ligand, S = spacer, dNTP = deoxyribonucleotide triphosphate derivative), is disclosed. Fluorescence detection after DNA amplification is used for detection of genetic mutations, oncogene mutations, in particular. A tetradentate  $\beta$ -diketonate **europium** chelate, 4,4'-bis(1'',1'',1'',2'',2'',3'', 3''-heptafluoro-4'',6''-hexanedion-6''-yl)- chlorosulfo-o-terphenyl (BHHCT)-Eu<sup>3+</sup>, was attached to a **streptavidin**-bovine serum albumin conjugate for **time-resolved** fluorometric detection of  $\lambda$  DNA by hybridization with a biotinylated probe DNA in a microtiter well. The method gave a detection limit of 23 pg/well (solid-phase measurement) and 4 pg/well (solution-phase measurement) for specific DNA.

AB A sensitive method for detecting  $17\beta$ -estradiol (E2) and estriol (E3) in river water was developed, based on the **time-resolved** fluoroimmunoassay by using a fluorescent Eu chelate label, 4,4'-bis(1'',1'',1'',2'',2'',3'',3''-heptafluoro-4'',6''-hexanedion-6''-yl)-chlorosulfo-o-terphenyl (BHHCT)-Eu<sup>3+</sup>. In the E2 assay, microtiter plates were coated with the E2-bovine serum albumin (BSA) conjugate. The anti- $17\beta$ -estradiol antibody, the biotinylated goat anti-rabbit IgG antibody and the BHHCT-Eu<sup>3+</sup> labeled **streptavidin** (SA)-BSA conjugate were used. In the E3 assay, the goat anti-rabbit IgG antibody was coated on a microtiter plate. The anti-estriol antibody and the BHHCT-Eu<sup>3+</sup> labeled E3-BSA conjugate were used. The detection limits for E2 and E3 were 2.3 pg/mL and 4.3 pg/mL, resp., and the anal. recoveries were 95-120%. Quant. measurement of estrogens in river water was carried out for Kanda River (Tokyo, Japan) by using the method. The E2 and E3 levels were 32 pg/mL and 5.5 pg/mL, resp. The detection limits of the present method are in the same orders of magnitude as those of ELISA for E2, and are 1-2 orders of magnitude better for E3.

AB Certain **lanthanide** chelate complexes are known to emit strong fluorescence with very distinct phys. properties that are different from those of organic fluorescent compds., as the fluorescence of

**lanthanide** complexes is long-lived with a half decay-time of several hundred microseconds to 2 ms. The complexes are excited by UV light and emit fluorescence in the visible region. The emission profile is very sharp and the wavelength is specific to each metal; for instance, Eu<sup>3+</sup> complexes emit at 615 nm and Tb<sup>3+</sup> complexes at 545 nm regardless of the ligand. These properties indicate **lanthanide** complexes can be excellent fluorescence labels for proteins and DNAs and provide highly sensitive detection methods in biotechnol. when **time-resolved** fluorometry is employed. Among many labels we have developed, BHHCT-Eu<sup>3+</sup> and BPTA-Tb<sup>3+</sup> are suitable for immunoassay, DNA hybridization assay, and DNA chip technol. Homogeneous DNA hybridization assay systems using fluorescence resonance energy transfer and fluorescence intercalators will be introduced.

AB 4,4''-Bis(1'',1'',1'''-trifluoro-2'',4''-butanedione-6'''-yl)-chlorosulfo-o-terphenyl (BTBCT) was synthesized by modifying the structure of the reported BHHCT. In comparison with the original BHHCT, the detection sensitivity of BTBCT-Eu chelate in aqueous solution was improved .apprx.8 times by **time-resolved** fluorescence measurement. To construct sensitive TRFIAs with the use of BTBCT-Eu chelate as the fluorescent label, **streptavidin**-BSA conjugate was prepared by the maleimide-thiol method and labeled by BTBCT. The **streptavidin**-BSA conjugate and its BTBCT-labeled complex were affinity-purified using 2-iminobiotin-agarose as binding reagent. With **streptavidin**-BSA-BTBCT-Eu complex as signal generation reagent, a highly sensitive

indirect serum hTSH TR-IFMA was developed. The low limit of detection (LLD) of the TSH TR-IFMA was 0.011 mIU/L with 10 µl of sample volume, corresponding to .apprx.337900 mols. per test. To evaluate the utility of BTBCT-Eu label in direct TRFIAs, a competitive serum T4 TRFIA was developed with T4-BSA-BTBCT-Eu complex as competing tracer. The measurements obtained by the present TSH TR-IFMA or T4 TRFIA correlated well with those obtained by com. Wallac TSH DELFIA Ultra or T4 DELFIA, resp. Primary results show that BTBCT can be employed as a powerful labeling material for constructing ultrasensitive TRFIAs.

AB A new nonadentate ligand, N, N, N1, N1-[2,6-bis(3'-aminomethyl-1'-pyrazolyl)-4-phenylpyridine]tetrakis(acetic acid) (BPTA) for a Tb3+ fluorescent complex was synthesized. The Tb3+ complex is strongly fluorescent, having a large fluorescence quantum yield of 1.00 and very long fluorescence lifetime of 2.681 ms in 0.05 M borate buffer of pH 9.1. **Streptavidin** (SA) was labeled with BPTA by using its succinimidyl monoester, and the BPTA-Tb3+-labeled SA was used in sandwich-type **time-resolved** fluoroimmunoassay (TR-FIA) of α-fetoprotein (AFP) and carcinoembryonic antigen (CEA) in human sera. The Tb3+-labeled SA was also used in competitive-type TR-FIA of bensulfuron-Me (BSM) in water. The detection limits of these assays are 42 pg/mL for AFP, 70 pg/mL for CEA, and 0.4 ng/mL for BSM. In addition, a new simultaneous measurement method for AFP and CEA in a human serum

sample was developed by using 4,4'-bis(1'',1'',1'',2'',2'',3'',3''-heptafluoro-4'',6''-hexanedion-6''-yl)chlorosulfo-o-terphenyl (BHHCT)-Eu3+-labeled anti-AFP antibody, biotinylated anti-CEA antibody, and BPTA-Tb3+-labeled SA. The concns. of AFP and CEA in 39 human serum samples were determined, and the results were compared with those of the independently determined AFP and CEA by TR-FIA with a single-label method. A good correlation was obtained with the correlation coeffs. of 0.991 for AFP and 0.994 for CEA.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB A novel simultaneous measurement method for  $\alpha$ -fetoprotein (AFP) and carcinoembryonic antigen (CEA) in human sera by **time-resolved** fluoroimmunoassay (TR-FIA) is described. The proposed approach combines the use of **europium**-labeled anti-AFP antibody for AFP TR-FIA and biotinylated anti-CEA antibody complexed to samarium-labeled **streptavidin** for CEA TR-FIA. A 96-well microtiter plate coated with a mixture of anti-AFP and anti-CEA monoclonal antibodies was used for the assay. After it was reacted with a solution containing AFP and CEA, a mixture of anti-AFP antibody labeled with BHHCT-Eu3+ and biotinylated anti-CEA antibody was added. The AFP concentration was determined by measuring the solid-phase fluorescence of the **europium**-labeled anti-AFP antibody at 615 nm. Then a BHHCT-Sm3+-labeled **streptavidin**-bovine serum albumin conjugate (SA-BSA) was added to react with the biotinylated anti-CEA antibody. After the reaction, the unreacted SA-BSA was washed out, and a 0.1 M NaOH solution containing  $1.0 \times 10^{-5}$  M TOPO and 0.05% SDS was added to dissociate the samarium-labeled SA-BSA in the immune complex on the surface of the well into the solution. The CEA concentration was determined by measuring the solution fluorescence of 643 nm from the samarium-labeled SA-BSA. The present method gives detection limits of 0.07 ng/mL for AFP and 0.3 ng/mL for CEA. The coefficient variations of the method are less than 7%, and the recoveries are in the range of 90-110% for serum samples. The AFP and CEA concns. in 27 human serum samples were determined by the present method as well as by single assay for comparison. A good correlation was obtained with the

correlation coeffs. of 0.990 for AFP and 0.973 for CEA. (c) 1999 Academic Press.

AB A simple and highly sensitive **time-resolved**  
fluoroimmunoassay of methamphetamine (MA) using a new fluorescent  
**europium** chelate (BHHCT-Eu<sup>3+</sup>) as a label is described. Two  
variations of competitive immunoassay were attempted. In the first  
(one-step) assay, microtiter plates coated with anti-MA were used, and the  
new label was bound to a conjugate of bovine serum albumin and  
N-(4-aminobutyl)-MA (MA-BSA). In the second (two-step) assay, instead of  
the labeled MA-BSA, biotinylated MA-BSA and BHHCT-Eu<sup>3+</sup>-labeled  
**streptavidin**-BSA were used. The lowest measurable concns. of MA  
for the one-step and the two-step methods were 1 ng/mL (25 pg/assay) and 1  
pg/mL (25 fg/assay), resp. These were 10 to 1000 times superior to the  
detection limits of MA in any other immunoassay. Intra-assay coefficient of  
variation was approx. 2-8% at eight different concns. (n = 4). Anal. of  
34 urine samples with the new method and conventional gas chromatog.  
showed a good correlation (r = 0.954). The high detectability of the  
present assay also enabled segmental hair anal. with a few centimeters of  
a hair.

LANGUAGE: English

AB A new chlorosulfonylated tetradentate  $\beta$ -diketone, 4,4'-bis(1'',1'',1''';2'',2'',3'',3''-heptafluoro-4'',6''-hexanedion-6''-yl)chlorosulfo-o-terphenyl (BHHCT), was synthesized as a chelating label for Eu<sup>3+</sup>. BHHCT can be covalently bound to proteins under mild conditions and forms a strongly fluorescent chelate with Eu<sup>3+</sup>. Bovine serum albumin (BSA) and **streptavidin** (SA) were labeled with BHHCH-Eu<sup>3+</sup>, and the latter was used for **time-resolved** fluoroimmunoassay of  $\alpha$ -fetoprotein (AFP) in human sera. A remarkably high sensitivity was obtained, with a detection limit of 4.1 + 10<sup>-3</sup> pg/mL, which corresponds to an improvement of about 4-5 orders of magnitude, compared to those of all conventional immunoassays including fluoroimmunoassay, enzyme immunoassay, and RIA. The high sensitivity was attained both by strong fluorescence of the present label and by the extremely suppressed background level brought about by the direct labeling of proteins with the  $\beta$ -diketone-Eu<sup>3+</sup> complex. A general consideration and ideas are given for designing ideal label ligands for strongly fluorescent Eu<sup>3+</sup> complexes.

AB A highly sensitive method is provided for detecting a **cytokine** (e.g., CXC chemokine, stromal-derived factor-1) in a body fluid (e.g., serum, whole blood) sample by a **time-resolved** fluorescence immunoassay (TR-FIA). The method comprises a process for forming on a solid phase a complex composed of a trapped **cytokine** and a fluorescent moiety forming a coordination structure with a **lanthanoid** metal (e.g., **europium**), and a process for measuring the fluorescence from the fluorescent moiety. The complex is formed by binding five components sequentially in this order: (a) a first antibody possessing a moiety bound to the solid phase and a region capable of binding with **cytokine**; (b) **cytokine**; (c) a second antibody possessing a region capable of binding with **cytokine** and a moiety bound with **biotin**; (d) a connector possessing streptavidin or avidin and a fluorescent moiety capable of forming a coordination structure with a **lanthanoid** metal ion; and (e) a **lanthanoid** metal ion. The fluorescent moiety (e.g., 4,4'-bis(1",1",1",2",2",3",3"-heptafluoro-4",6"-hexadione-6"-yl)-sulfo-o-terphenyl) is represented by the general formula 3,5-(C3F7COCH2CO-p-C6H4)C6H3SO3N.
